THE HEAT-CENTRE IN THE BRAIN.

By ISAAC OTT, M.D.

WENTY years ago it was announced by Tscheschichin that a heat-centre existed above the pons Varolii in the brain. Prof. H. C. Wood, in his large work on fever, has also by numerous experiments arrived at the same conclusion regarding the presence of a cerebral heatcentre. Richet also discovered that the anterior part of the brain had an influence on the temperature of the body. The position of this centre was not located till I published a communication, April 2d, 1884, stating that it was about the corpora striata. Drs. Aronsohn and Sachs in December, 1884, discovered that puncture in the brain caused an increase of the temperature of the body. On July 4th, 1885, I published a preliminary communication, stating that the heat-centre could be localized at the anterior inner end of the optic thalami and that the increase of temperature was due to increased production of heat. On Oct. 20th, 1885, Drs. Sachs and Aronsohn published a paper stating that the heat-centres were more accurately localized in the nodus corsorius and the tissues about the corpus striatum, and that the increase of temperature was due to increased heat-production. In this paper I propose to give the experiments upon which the preliminary note was based.

Forty experiments were made upon rabbits. The ani-

mal was bound down, the scalp divided and the skull trephined, the dura mater divided, and punctures made through the brain by means of a small spear-pointed instrument two millimetres in diameter at the point and the remaining part one millimetre in thickness. The temperature-variations were noted by means of a rectal thermometer. The animal during this time was permitted to run about the laboratory. Punctures were also made upwards through the base of the brain by means of a stiff probe which passed through the skull by pressure. After all these punctures the animal was killed, the brain removed, hardened in alcohol, and sections made. To estimate heat-production, d'Arsonval's copper-calorimeter, surrounded by means of felt and feathers, was employed. The temperature of the calorimeter was noted by means of a thermometer inserted into the water contained in its closed cavity. Another thermometer inserted into the exit tube gave the temperature of the air aspirated from the calorimeter by means of the large meter of the Voitrespiration apparatus, which is run by a water-wheel. The temperature of the air of the room was also noted. The calorimeter was used when its temperature was a few degrees below that of the air. The large meter registered the amount of air passing through the meter. The calculations were made in the manner detailed in Wood's work on fever. All thermometers were corrected before the estimates were made. If the appended experiments are examined, it will be seen that at the anterior inner end of the optic thalamus a puncture causes a great increase of temperature in Exp. 12, almost 7° F. in an hour. this rise of temperature continues on the following day is seen in several experiments, as in Exp. 8.

The calorimeter experiments show that the increments of temperature are due to increased production of heat and not to diminished dissipation.

In Exp. 16, the increase was 11.13 units; in Exp. 17, 10.49 units. In the calorimeter experiments, a great increase of temperature was not obtained, otherwise the units of heat-production would be much greater. Many

other calorimetrical experiments were made, but I do not think it necessary to publish them, as they are only confirmatory of those noted. Electric irritation by means of Du Bois-Reymond's inductorium caused an increase of temperature. It was also found that Fairchild's trypsin when dissolved in water with a small quantity of bicarbonate of soda and filtered, that the filtrate injected by the jugular caused a rise of temperature of four degrees in the rabbit.

These experiments prove that at the anterior inner end of the optic thalami a puncture causes an increase of temperature due to increased heat-production. Fig. A—I shows about the point that the puncture should be made to cause the greatest increase of temperature; 2, is the corpus striatum; 3, optic thalamus; 4, corpora quadri-

gemina; 5, cerebellum. The cut was drawn by my student, Mr. Carter, from the brain of a rabbit.

Experiments made during last summer show that the tissues between the optic thalami and corpora striata along the median line also cause an increase of temperature, especially at the point which Schiff has pointed out as causing upon injury in rabbits a peculiar cry.

We have here an artificial fever due entirely to nervous disturbance, and not to any poisons circulating in the blood. The rise of 7° F. in an hour shows that the nervous system plays a very extended part in the phenomena of fever. As to the nature of these centres, all opinions are more or less conjectural. With our present information on other functions of the brain, the inference is that they are inhibitory in their nature.

1061n

I am indebted to my student, Mr. Peter J. Martin, for the calorimetrical determinations.

For every degree the calorimeter is below that of the air, a correction of τ_{00} ° F. is made for the rise of temperature of the calorimeter during the experiment. It was found by several experiments that the calorimeter normally rose this much every hour, when a definite quantity of air was drawn through the calorimeter.
